## LIST OF TABLES

Table 1. Region E white spruce clonal seed orchard (G259C) – cone and seed production.....	5
--	---

## **1.0 INTRODUCTION**

The Region E seed orchard is located at the Alberta Tree Improvement and Seed Centre (ATISC) site and is managed and maintained by ATISC. It occupies an area of approximately 2.5 hectares and is designed for 1200 grafts. The orchard was established in 2 phases: planting of Phase I (G259A), designed for 700 grafts, commenced in 1989; Phase II (G259B), with a capacity of 500 grafts, was initially planted in 1995. Since 2003, the orchard has been considered a single production facility with the project number G259C. This is a rolling front orchard in which clones are replaced on a more or less continuous basis as higher breeding value material is identified; the number of clones finally represented will reflect a balance between gain and effective population size. The first genetic roguing of the orchard was done in 2005 based on progeny test results for 11 year height.

The Controlled Parentage Plan (CPP) related to this orchard is the Region E White Spruce Tree Improvement Project in the Northeast Boreal Lowland Region in Alberta.

The base population for this CPP is considered to be wild stands of white spruce occurring within Region E. The current breeding population consists of 119 wild stand selections, 3 plantation selections from the G103 white spruce provenance trials and 5 forward selections from the Region E progeny trial at the Wandering River site (G156B). As of September 2010, 1142 grafts representing 97 of these parents are established in the orchard.

The progeny trials for this CPP, assigned project number G156, were established in 1994 at Kinosis Lake (G156A), Wandering River (G156B) and Calling Lake (G156C). These trials were 19 years old at the end of the 2010 growing season.

The orchard manager is Mike Storp (ATISC) with scientific support from Jill Makim (ATISC).

This report provides highlights of the management and operations of the seed orchard in 2010. A point form summary of activities in 2010 is provided in Appendix A.

## **2.0 CULTURAL ACTIVITIES**

### **2.1 Irrigation**

The irrigation system was activated on May 19. All lines were flushed and emitters to all grafts were checked to ensure free water flow.

The orchard is normally irrigated every week for 8 to 16 hours depending upon rainfall. Throughout the summer, the system was inspected periodically to ensure that all trees were being sufficiently irrigated. Repairs were made as required.

On October 13, the orchard was given a final deep watering to at least eight inches below the soil surface.

## **2.2 Fertilization**

Based on soil sample analyses completed on October 5, 2009, a fertilizer prescription specific to the Region E orchard was developed for the 2010 growing season. A blend of 21-0-0, 46-0-0, 0-45-0 and 0-0-51 was used. The prescribed amount of fertilizer was applied over three applications completed in October (2009), June (2010) and July (2010). Fertilizer is applied with a band fertilizer that places a 50 cm band on both sides of the graft. The fertilization workplan for 2010 is in Appendix B.

On September 27, 2010, soil and tissue samples were taken to assess the macro- and micro- nutrient levels of the soil and the current year's growth of the grafts. The fertilizer prescription for the 2011 growing season is based on these assessments. Soil sampling was conducted throughout the orchard, at a depth of six inches and within one foot of planted grafts. Both samples were submitted to an accredited laboratory for detailed nutrient analysis.

## **2.3 Vegetation Management and Control**

Mowing was done three times during the growing season on June 4, 7-8, July 5-6 and 21.

## **2.4 Flower Induction**

No flower induction activities were undertaken in 2010.

## **2.5 Supplemental Pollination**

No supplemental pollination was undertaken in 2010.

## **2.6 Graft Maintenance**

No major graft maintenance was completed in 2010 in the orchard.

Throughout the growing season, active northern pocket gophers (*Thomomys talpoides*) were trapped using a box trap. The gophers are tunnelling under established grafts, loosening the soil and damaging roots causing the grafts to fall over.

## **3.0 INSECT AND DISEASE INCIDENCE**

Inspections for insect and disease problems were carried out in conjunction with regular maintenance activities.

On June 21, a moderate infestation of yellow headed spruce sawfly (*Pikonema alaskensis*) was noted and Entrust<sup>®</sup> 80W Naturalyte (Spinosyn) was applied at a rate of 15 gms/1000 L (1.5% solution) using a tractor turbo mist sprayer. Throughout the summer, periodic checks were made to ensure outbreaks of this insect did not reoccur.

In a sample of 300 mature cones the spruce cone maggot (*Strobilomyia neantracina*) and the spruce cone axis midge (*Kaltenbachiola rachiphaga*) were identified. Especially damaging was the cone maggot which was detected in 18% of the cones; seed loss due to the maggot was estimated at about 12%. The cone axis midge was found in one cone only.

## **4.0 ORCHARD MONITORING AND RESEARCH**

### **4.1 Permanent Sample Trees**

As a requirement of the Forest Genetic Resource Management and Conservation Standards (FGRMS), permanent sample trees (PST) are assigned in the seed orchard to provide orchard specific data about orchard development, flowering, cone and seed production, and seed quality. They also provide an estimate of reproductive gender balance and data for cone crop forecasting. A minimum of 10% of orchard trees are designated as PSTs and they represent each clone and planting year (see Appendix 33 FGRMS). Data recorded on PSTs include total height, crown width, diameter at breast height (dbh), flower and cone production, seed yield and germination. In 2010, 137 PSTs were assessed and the data are summarized in Appendix C.

### **4.2 Phenology Monitoring**

Phenology monitoring permits the identification of clones that are receptive either later or earlier than the bulk of the orchard population. It also allows the period of orchard receptivity to be related to patterns of within orchard pollen flight. Clones that may not be successfully pollinated can then be identified.

Assessments of female and male bud development begin when most reproductive buds are identifiable and are continued until all sample trees are post-receptive and pollen has flown. Data are collected approximately every 2 days. Orchard phenology is monitored with the PSTs.

In 2010, female phenological development was assessed on 108 PSTs representing 54 clones and male phenological development was assessed on 124 PSTs representing 62 clones. The first assessment was done on May 10 when growing degree days (GDD) had reached 73; the last assessment was on May 19 at 160 GDD. Based on the phenology data, the period of orchard receptivity (when at least 20% of the clones are receptive) was estimated to be May 14 to 18 corresponding to accumulated GDD of 95-147. Pollen trap data show that pollen flight in the orchard peaked May 17-18 (129-147 GDD). On average, clones were receptive for 4.5 days and shedding pollen for 2.1 days.

The phenology data suggest that most clones reach receptivity 2-3 days in advance of general pollen flight in the orchard. On the contrary, the pollen trap data indicate that the beginning of pollen flight and female receptivity are essentially concurrent. In either case, all clones in the PST sample remained receptive throughout the orchard pollen flight period and, since pollen flight both within and outside the orchard is essentially concurrent, there should be no increased risk of pollen contamination resulting from incomplete synchrony between receptivity and pollen flight in the orchard.

Data and summaries appear in Appendix E.

### **4.3 Pollen Monitoring**

Wind vane type pollen monitors are used to determine the period of pollen flight and pollen cloud density. The data are used to estimate the level of pollen contamination in the seed orchard.

Three monitors are installed in the orchard and four regional monitors are located north (D1), south (E sector), northeast (culverts) and southeast (burn pit) of the orchard (Appendix D). Because a jack pine stand occurs to the west of the orchard, no suitable openings are available for establishing a pollen monitor within a reasonable distance of the orchard in this direction.

A microscope slide coated with Vaseline<sup>®</sup> is mounted on each monitor to trap pollen. The monitors are installed in early May, before the start of pollen release, and the slides are changed every 1-2 days.

Pollen cloud density is determined by examining the slides using a compound microscope fitted with a 10x eye piece lens and a 10x objective lens giving a total magnification of 100x. A 1 cm<sup>2</sup> micrometer grid is inserted into the eyepiece and the number of pollen grains falling within the grid is counted. Pollen grains are magnified 100x; the micrometer grid in the eyepiece is 1 cm<sup>2</sup> magnified 10x which is equivalent to 1 mm<sup>2</sup> magnified 100x, therefore, counts are in grains/mm<sup>2</sup>. Counts are done on 10 systematically selected fields on the microscope slide and averaged over all orchard or regional monitors to give average pollen density for a given day.

Pollen was trapped from May 14 to June 1. From May 14 to 18, the period of orchard receptivity, an average of 20.9 spruce pollen grains/mm<sup>2</sup> were trapped on the orchard monitors and 6.4 spruce pollen grains/mm<sup>2</sup> were trapped on the regional monitors. Pollen contamination was estimated at 10%. A summary of the data and the pollen contamination calculations are provided in Appendix F.

### **5.0 CONE AND SEED PRODUCTION**

Cone collection commenced on August 18 and was completed by August 24. Tripod ladders and two 40-foot manlifts were used in cone picking operations. Trees 5-6m in height were topped to facilitate cone collection. Cones were picked directly into a 1 or 2 gallon pail equipped with a quick release clip and chain to allow easy placement on the ladder or the tree.

#### Non-PST Trees (Bulk collection):

Cones from non-PST trees were bulked into burlap sacks and brought to the Smoky Lake Forest Nursery (SLFN) seed cold storage bays for volume measurement and curing.

#### PST collection:

Cones from PSTs were collected and bagged separately in order to estimate the effective population size of the 2010 orchard seedlot (see FGRMS Appendix 37). ATISC staff measured the cone volume of each individual tree collection unless the number of cones was very small (i.e. <15). For collections less than 2 litres, all the cones were counted; for collections greater than 2 litres, the number of cones in 1 litre was counted and the total number of cones estimated by multiplying total volume by cones per litre. Cones were then bulked and spread on screen-lined pallets to cure. On October 13, the cones were released to SLFN for extraction and testing.

In 2010, the orchard produced 3160 litres of cones and 26.21 kilograms of clean seed with a germination of 92%. Annual information on orchard development, cone and seed production, seed testing and effective

population size is summarized in Table 1. Beginning in 2010,  $N_e$  is estimated from PST data instead of from the entire cone crop. The genetic worth of the 2010 seed crop is estimated at 2.5% without adjusting for pollen contamination; after adjusting for 10% pollen contamination the genetic worth is 2.3%.

Table 1. Region E white spruce clonal seed orchard (G259C) – cone and seed production.

Variable	2010	2009	2008	2007	2006	2005	2004	2003	2002	2001	2000

<sup>1</sup>estimated from psts

\*\* $N_e$  includes polycross collections from 14 clones which were extracted and stored separately from the bulk collection for use in progeny testing  
 $N_e$  excluding these clones is 25.1; this is the  $N_e$  of the bulk seedlot in operational cold storage

## 6.0 SUBSEQUENT YEARS' PLANNING

Based on 15-year analysis results, the orchard will be rogued and redesigned to increase representation of top performing parents.

## **Appendix A.**

## **Operations Completed for 2010 – Brief Summary**

April 1	Pollen slides preparation for 2010 pollen flight
April 28	Graft assessment and check 2009 planting
April 30	Graft maintenance
May 3	Install pollen traps
May 10	Phenology survey

## **Appendix G. 2010 G259C Addendum**

### **ALBERTA TREE IMPROVEMENT PROGRAM**

### **SUSTAINABLE RESOURCE DEVELOPMENT**

#### **ADDENDUM TO G259C (2010)**

**Project Title:** Region E White Spruce Clonal Seed Orchard – Phase III

**Planting:** Planting of 5 grafts representing 2 clones took place on July 12, 2010. Holes were dug with shovels and rootballs were slashed to promote growth. Bone meal (50 grams) was added to each planting hole to improve rooting. Spaghetti tubing and emitters for above ground irrigation were connected and water was supplied to the grafts immediately after planting. Weather at the time of planting was 22°C. Planting was completed in the early morning.

At the end of the 2010 growing season, there were 1142 grafts established representing 97 clones. The orchard is 95.17% filled based on the orchard capacity of 1200.

**Mortality:** No mortality occurred in the seed orchard in 2010.

**Planters:** Margo Weirn and Erik Toews.

Mike Storp  
November 18, 2010
